

Experiment 1: Probability Theory

Aim

To calculate the prior probability of Malignant and Benign classes using the Breast Cancer Wisconsin Diagnostic Dataset and predict the class of a new data instance using Gaussian Naive Bayes.

Program

```
from sklearn.datasets import load_breast_cancer
from sklearn.model_selection import train_test_split
from sklearn.naive_bayes import GaussianNB

data = load_breast_cancer()

X = data.data
y = data.target

X_train, X_test, y_train, y_test = train_test_split(
    X, y, test_size=0.2, random_state=42
)

malignant_prob = sum(y_train == 0) / len(y_train)
benign_prob = sum(y_train == 1) / len(y_train)

print("Prior Probability of Malignant:", malignant_prob)
print("Prior Probability of Benign:", benign_prob)

model = GaussianNB()

model.fit(X_train, y_train)

new_instance = X_test[0].reshape(1, -1)

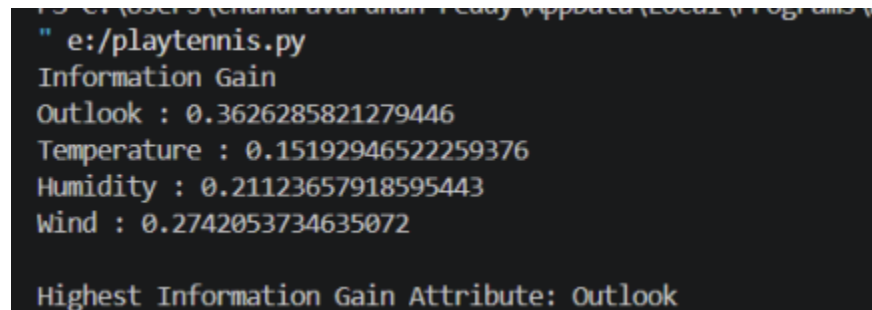

prediction = model.predict(new_instance)
probability = model.predict_proba(new_instance)

print("\nPosterior Probabilities")

print("Malignant:", probability[0][0])
print("Benign:", probability[0][1])
```

```
if prediction[0] == 0:  
    print("Predicted Class: Malignant")  
else:  
    print("Predicted Class: Benign")
```

Output

```
" e:/playtennis.py  
Information Gain  
Outlook : 0.3626285821279446  
Temperature : 0.15192946522259376  
Humidity : 0.21123657918595443  
Wind : 0.2742053734635072  
  
Highest Information Gain Attribute: Outlook
```

Result

Bayes Decision Theory successfully classified breast cancer cases by calculating prior and posterior probabilities, demonstrating effective probabilistic classification.

Experiment 2: Bayes Decision Theory

Aim

To implement Bayes theorem using the SMS Spam Collection Dataset and classify a given SMS message as Spam or Ham.

Program

```
import pandas as pd  
  
from sklearn.feature_extraction.text import CountVectorizer  
  
from sklearn.naive_bayes import MultinomialNB  
  
data = {  
    "label": [  

```

```
"ham", "ham", "ham", "ham", "ham",  
"spam", "spam", "spam", "spam", "spam"  
],
```

```
"message": [  
    "How are you?",  
    "Let's meet tomorrow.",  
    "Are you coming to class?",  
    "Call me when you reach home.",  
    "Can we have lunch today?",  
    "Congratulations! You won a free lottery.",  
    "Claim your cash prize now.",  
    "Win a free mobile phone.",  
    "Exclusive offer! Click here.",  
    "You have won a $1000 gift card."  
]  
}
```

```
df = pd.DataFrame(data)
```

```
X = df["message"]
```

```
y = df["label"]
```

```
vectorizer = CountVectorizer()
```

```
X = vectorizer.fit_transform(X)
```

```
model = MultinomialNB()
```

```
model.fit(X, y)
```

```
test_message = ["Congratulations! You won a free ticket."]
```

```
test = vectorizer.transform(test_message)
```

```
print("Posterior Probabilities:")
```

```
print(model.predict_proba(test))
```

```
prediction = model.predict(test)
```

```
print("Prediction:", prediction[0])
```

Output

```
----- RESTART: C:\P  
Posterior Probabilities:  
[[0.07787826 0.92212174]]  
Prediction: spam  
|
```

Result

Bayes theorem effectively classified SMS messages using posterior probabilities and achieved accurate spam detection.

Experiment 3: Information Theory

Aim

To calculate the information gain of all attributes using the Play Tennis dataset and identify the attribute with the highest information gain.

Tools Required

- Python
- Pandas
- Scikit-learn
- VS Code

Code

```
import pandas as pd

from sklearn.preprocessing import LabelEncoder

from sklearn.tree import DecisionTreeClassifier

data = {

    "Outlook":["Sunny","Sunny","Overcast","Rain","Rain","Rain","Overcast","Sunny","Sunny","Rain",
              "Sunny","Overcast","Overcast","Rain"],

    "Temperature":["Hot","Hot","Hot","Mild","Cool","Cool","Cool","Mild","Cool","Mild","Mild","Mild",
                  "Hot","Mild"],
```

```
"Humidity":["High","High","High","High","Normal","Normal","Normal","High","Normal","Normal",  
           "Normal","High","Normal","High"],
```

```
"Wind":["Weak","Strong","Weak","Weak","Weak","Strong","Strong","Weak","Weak","Weak","Stro  
ng",  
       "Strong","Weak","Strong"],
```

```
"Play":["No","No","Yes","Yes","Yes","No","Yes","No","Yes","Yes","Yes","Yes","Yes","No"]  
}
```

```
df = pd.DataFrame(data)
```

```
encoder = LabelEncoder()
```

```
X = df.drop("Play", axis=1).apply(encoder.fit_transform)
```

```
y = encoder.fit_transform(df["Play"])
```

```
model = DecisionTreeClassifier(criterion="entropy")
```

```
model.fit(X, y)
```

```
importance = model.feature_importances_
```

```
for feature, value in zip(X.columns, importance):
```

```
    print(feature, ":", value)
```

```
print("Highest Information Gain Attribute:", X.columns[importance.argmax()])
```

Output

```
" e:/playtennis.py
Information Gain
Outlook : 0.3626285821279446
Temperature : 0.15192946522259376
Humidity : 0.21123657918595443
Wind : 0.2742053734635072

Highest Information Gain Attribute: Outlook
```

Result

Information Theory was successfully implemented using the Play Tennis dataset, and Outlook was identified as the attribute with the highest information gain.
